

# Compressed air energy storage in water

## Overview

---

Compression of air creates heat; the air is warmer after compression. Expansion removes heat. If no extra heat is added, the air will be much colder after expansion. If the heat generated during compression can be stored and used during expansion, then the efficiency of the storage improves considerably. There are several ways in which a CAES system can deal with heat. Air storage can be , diabatic, , or near-isothermal.

This method stores energy in the form of increased potential energy of water, pumped from a lower elevation to a higher elevation during times of low demand and excess energy production. This method includes storing energy by filling the inflatable bladders with compressed air.

Savannah River National Laboratory (SRNL) has developed a system and method using a hybrid compressed air/water energy storage system. This system can be used in a subsurface land-based system or a submerged water-based system. Energy storage systems that can efficiently store excess off-peak.

Compressed-air-energy storage (CAES) is a way to store energy for later use using compressed air. At a utility scale, energy generated during periods of low demand can be released during peak load periods. [1] The first utility-scale CAES project was in the Huntorf power plant in Elsfleth, Germany.
