

Electromagnet energy storage

Overview

Superconducting magnetic energy storage (SMES) systems are created by the flow of current in a coil that has been cooled to a temperature below its critical temperature. This use of superconducting coils to store magnetic energy was invented by M. Ferrier in 1970. A typical SMES system includes three parts: superconducting coil, power conditioning system and an energy storage system. SMES systems can store energy for up to 3 hours with an efficiency of 95%.

The principles of electromagnetic energy storage are fundamentally based on two key components: capacitance and inductance. Capacitors serve to store electrical energy in the form of an electric field, while inductors are designed to store energy through magnetic fields.
