

Photosynthetic energy storage

Overview

In natural photosynthesis, photosynthetic organisms such as green plants realize efficient solar energy conversion and storage by integrating photosynthetic components on the thylakoid membrane of chloroplasts.

Despite the low efficiency, the amount of energy stored by photosynthesis each year in the biosphere is still roughly four times that of the annual consumption by humans [1]. The fossil fuels we use today are all made from ancient photosynthesis. Coal, petroleum, and natural gas are decomposition.

The conversion of sunlight into chemical energy by photosynthesis is the basic biological process driving life on Earth. Photosynthesis sustainably generates food, feed, energy-rich biomolecules, soil organic carbon, and fossil fuels over geological time, while sequestering atmospheric CO₂. An.
