This review highlights recent progress in the development of lithium-ion batteries, supercapacitors, and battery-supercapacitor hybrid devices. Afterward, various materials applicable to create the above electrochemical energy storage devices are highlighted.

We propose a microstructural strategy with dendritic nanopolar (DNP) regions self-assembled into an insulator, which simultaneously enhances breakdown strength and high-field polarizability and minimizes energy loss and thus markedly improves energy storage performance and stability.

This measure directly quantifies the energy gap between the maximum and minimum energy states of the quantum battery. Its calculation is straightforward and does not require time-dependent optimization, making it suitable for both open and closed quantum batteries.

Nowadays, the energy storage systems based on lithium-ion batteries, fuel cells (FCs) and super capacitors (SCs) are playing a key role in several applications such as power generation, electric vehicles, computers, household, wireless charging and industrial drives systems.
