## Overview

---

Superconducting magnetic energy storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil that has been cryogenically cooled to a temperature below its superconducting critical temperature. This use of superconducting coils to store magnetic.

There are several reasons for using superconducting magnetic energy storage instead of other energy storage methods. The most important advantage of SMES is that the time delay during charge and discharge is quite short.

There are several small SMES units available for use and several larger test bed projects. Several 1 MW·h units are used for control in installations around the world, especially to provide power quality at manufacturing plants requiring ultra.

Besides the properties of the wire, the configuration of the coil itself is an important issue from a aspect. There are three factors that affect the.

Under steady state conditions and in the superconducting state, the coil resistance is negligible. However, the refrigerator necessary to keep the superconductor cool requires electric.

A SMES system typically consists of four partsSuperconducting magnet and supporting structureThis system includes the.

As a consequence of , any loop of wire that generates a changing magnetic field in time, also generates an . This process takes energy out of the wire through the (EMF). EMF is defined as electromagnetic work.

Whether HTSC or LTSC systems are more economical depends because there are other major components determining the cost of SMES: Conductor consisting of superconductor and.
